On this project, called "Full-Time Solar", the companies plan to use a wind-powered energy storage system to simulate the fluctuating solar power from a number of large-scale solar plants by adding that extra wind power to supply peak electricity demand. The solar industry is in the midst of a cost drop that is making solar power increasingly competitive with coal- and gas-fired power. Currently, Germany produces more than 20 percent of its electricity from solar power. The E.ON and RWE plan to build 100 megawatts of solar plants with a total capacity of 500 megawatts. "A quarter-century ago, there was a world crisis over an oil crisis. We need to approach this in a similar way," said E.ON CEO Andreas Goeldler. The E.ON and RWE are experimenting with an energy system that would be built on a 1500-megawatt power plant in the Rhine River valley. That would be the equivalent of 200,000 average-sized houses being replaced with solar plants. The project calls for four small solar farms with a total capacity of 20 megawatts that would be built on a wind farm with a total capacity of 1.5 gigawatts. A 5-megawatt-hour battery bank would be set up in Geesthacht, Germany, to store solar energy in the form of electricity generated by wind turbines and returned to the electricity grid. The firm plans to transmit the electricity to a transmission power line that travels along the Rhine River from Geesthacht to Niederrissen. On the reception side, solar plants would be built in Niederrissen and Hilden that would be equipped with another 1.5-gigawatt wind power plant. The total capacity of
