Intracerebral and intraventricular transplantation of human embryonic stem cell-derived neural progenitor cells improves neurogenesis, axon regeneration, and functional recovery after stroke in mice. Neural progenitor cells (NPCs) derived from human embryonic stem cells (hESCs) are a promising therapeutic option for regenerative medicine. However, their optimal use is still under debate. Whether NPCs from hESCs can survive and differentiate in the brain and promote neurogenesis remains unknown. In this study, to investigate whether these NPCs could survive and differentiate in the brain, we transplanted NPCs into the cortices or right ventricles of the brains of mice subjected to transient middle cerebral artery occlusion (MCAo). The results showed that hESC-derived NPCs could survive and differentiate in the brain, and that their intraventricular transplantation not only enhanced neural progenitor cell (NPC) differentiation, but also improved axon regeneration and functional recovery. To investigate the association between endothelin-1 (ET-1) promoter gene polymorphisms and systemic lupus erythematosus (SLE) susceptibility in Asians, we performed a case-control study in 168 SLE patients and 205 controls. We detected a significant difference in the distribution of the A/G polymorphism between patients and controls ($p = 0.014$) and a positive association of the G allele with SLE in our study population. The odds ratio for SLE was 2.80 (95% CI 1.14-6.85) after adjustment for gender. The G allele was significantly more common in patients with nephritis (OR 3.45, $p = 0.005$) and Raynaud's phenomenon (OR 4.45, $p = 0.001$) than in patients without these disorders. The distribution of other polymorphisms in the ET-1 gene showed no significant association with SLE. Our results suggest a possible role of the ET-1 G/A polymorphism as a genetic risk factor for SLE in Asians.Q: Change Datagridview cell value at runtime I want to 6d1f23a050
